PH 716 Applied Survival Analysis

Part IV: Accelerated Failure Time Model

Zhiyang Zhou (zhou67@uwm.edu, zhiyanggeezhou.github.io)

2024/Feb/12 16:53:52

Assumptions

- T_i are independent across i
 - NO longer assumed to share the identical distribution
 - i.e., "personalized" or "individualized"
- log-linear model: $\ln T_i = \beta_0 + \sum_{j=1}^p x_{ij} \beta_j + \sigma \varepsilon_i$ Unknown parameters $\sigma > 0$ and $\beta_j \in \mathbb{R}$

 - Error terms ε_i are iid
- Equiv. $T_i = \exp(\beta_0 + \varepsilon_i) \prod_{j=1}^p \exp(x_{ij}\beta_j)$
 - (Why is called "accelerated failure time model"?) The effect of covariates acts multiplicatively on the survival time and accelerates or decelerates the progress along the time axis.

Parameter interpretation

- β_0 is the baseline of logarithm of survival times. This baseline refers to the scenario where the effect of covariates is neutral (i.e., all β_i , j > 0, are all zeros).
- The interpretation of β_j , j > 0, is based on controlling covariates associated with other coefficients, i.e., $x_{i1},\ldots,x_{i,j-1},x_{i,j+1},\ldots,x_{ip}.$
 - Holding values of other covariates, a unit increase in x_{ij} corresponds to an increase of β_i in the mean of $\ln T_i$. More specifically, it shifts the distribution of $\ln T_i$ to the left by the amount β_i . Or, equivalently, all percentiles of the distribution of $\ln T_i$ are shifted to the left by β_i . Correspondingly, the percentiles of T_i are multiplied by the constant e^{β_j} .

Survival function

- If $\varepsilon_i \stackrel{iid}{\sim} N(0,1)$, $-S_{T_i}(t) = \Pr(\ln T_i > \ln t) = \Pr\{\varepsilon_i > \sigma^{-1}(\ln t - \beta_0 - \sum_{j=1}^p x_{ij}\beta_j)\} = 1 - \Phi\{\sigma^{-1}(\ln t - \beta_0 - \sum_{j=1}^p x_{ij}\beta_j)\} = 1 - \Phi\{\sigma^{-1}(\ln t - \beta_0 - \sum_{j=1}^p x_{ij}\beta_j)\}$

 - $\begin{array}{l} \sum_{j=1}^{p} x_{ij} \beta_{j}) \} \\ * \Phi(\cdot): \text{ the cdf of } N(0,1) \\ \text{ i.e., } T_{i} \sim \text{log-normal}(\beta_{0} + \sum_{j=1}^{p} x_{ij} \beta_{j}, \sigma^{2}) \end{array}$
- If $\varepsilon_i \stackrel{iid}{\sim}$ the standard Gumbel distribution for minimum (i.e., $F_{\varepsilon_i}(\epsilon) = 1 \exp(-\exp(\epsilon))$,
 - P.S. $\min(X_1, X_2, \dots, X_n) \ln n \xrightarrow{d} \text{standard Gumbel distribution (for minimum) as } n \to \infty \text{ if}$ $X_i \stackrel{iid}{\sim} \exp(1)$
 - $-S_{T_i}(t) = \Pr\{\varepsilon_i > \sigma^{-1}(\ln t \beta_0 \sum_{j=1}^p x_{ij}\beta_j)\} = 1 F_{\varepsilon_i}\{\sigma^{-1}(\ln t \beta_0 \sum_{j=1}^p x_{ij}\beta_j)\} =$ $\exp[-t^{1/\sigma}\exp\{-(\beta_0 + \sum_{j=1}^p x_{ij}\beta_j)/\sigma\}] = \exp[-\{t/\exp(\beta_0 + \sum_{j=1}^p x_{ij}\beta_j)\}^{1/\sigma}]$ - i.e., $T_i \sim$ Weibull with $1/\sigma$ as the "shape" and $\exp(\beta_0 + \sum_{j=1}^p x_{ij}\beta_j)$ as the "scale"
 - - * Widely used in practice, with a hazard descending or ascending with respect to t
 - * Specifically, $T \sim$ exponential if $\sigma = 1$, with a hazard constant with respect to hazard

Likelihood principles (for uncensored data)

- Observed $T_1 = t_1, \ldots, T_n = t_n$
- Joint density of $\mathbf{T} = [T_1, \dots, T_n]^{\top}$ evaluated at $[t_1, \dots, t_n]^{\top}$: $f_{\mathbf{T}}(t_1, \dots, t_n; \boldsymbol{\theta})$
 - $-\theta$: a p-vector of unknown parameters
- Observed-data likelihood $L(\boldsymbol{\theta}) = f_{\mathbf{T}}(t_1, \dots, t_n; \boldsymbol{\theta})$
 - Taken as a function of θ
 - $-L(\boldsymbol{\theta}) = \prod_{i=1}^n f_{T_i}(t_i; \boldsymbol{\theta})$ if T_i is independent across if
- Maximum likelihood estimator (MLE): $\hat{\theta}_{\text{ML}} = \max_{\theta} L(\theta) = \max_{\theta} \ell(\theta)$
 - $-\ell(\boldsymbol{\theta}) = \ln L(\boldsymbol{\theta})$
 - A closed-form solution for $\hat{\boldsymbol{\theta}}_{\mathrm{ML}}$ usually not available
 - * Resorting to numerical optimization techniques, e.g., Newton's method
- Confidence interval (CI) of θ
 - $-\hat{\boldsymbol{\theta}}_{\mathrm{ML}} \approx N(\boldsymbol{\theta}, I(\hat{\boldsymbol{\theta}}_{\mathrm{ML}})^{-1})$ for iid T_i
 - * Because $\sqrt{n}(\hat{\boldsymbol{\theta}}_{\mathrm{ML}} \boldsymbol{\theta}) \stackrel{d}{\to} N(0, nI(\boldsymbol{\theta})^{-1})$ for iid T_i
 - * Fisher information (the expectation of Hessian matrix of $\ell(\boldsymbol{\theta})$): $I(\boldsymbol{\theta}) = -\mathrm{E} \frac{\partial^2 \ell(\boldsymbol{\theta})}{\partial \boldsymbol{\theta} \partial \boldsymbol{\theta}^{\top}} \approx -\frac{\partial^2 \ell(\boldsymbol{\theta})}{\partial \boldsymbol{\theta} \partial \boldsymbol{\theta}^{\top}} \approx -\frac{\partial^2 \ell(\boldsymbol{\theta})}{\partial \boldsymbol{\theta} \partial \boldsymbol{\theta}^{\top}}$
- Likelihood ratio test (LRT)
 - $-H_0$ vs H_1
 - Test statistic: $-2 \ln \frac{L(\hat{\boldsymbol{\theta}}_{\text{ML},H_0})}{L(\hat{\boldsymbol{\theta}}_{\text{ML}})} = 2\{\ell(\hat{\boldsymbol{\theta}}_{\text{ML}}) \ell(\hat{\boldsymbol{\theta}}_{\text{ML},H_0})\}$
 - * $\hat{\boldsymbol{\theta}}_{\mathrm{ML},H_0}$: the (constrained) MLE under H_0
 - * $\hat{\boldsymbol{\theta}}_{\mathrm{ML}}$: the MLE under $H_0 \bigcup H_1$
 - Reject H_0 if the value of $-2 \ln \frac{L(\hat{\boldsymbol{\theta}}_{\text{ML},H_0})}{L(\hat{\boldsymbol{\theta}}_{\text{ML}})}$ is over $\chi^2_{p,1-\alpha}$ * $\chi^2_{p,1-\alpha}$: the $1-\alpha$ quantile of $\chi^2(p)$

 - * Because $-2 \ln \frac{L(\hat{\boldsymbol{\theta}}_{\text{ML},H_0})}{L(\hat{\boldsymbol{\theta}}_{\text{ML}})} \approx \chi^2(p)$ · p: the difference of free parameters with and without H_0

Ex. 4.1 (uncensored exponential-distributed observations)

• The following n=10 iid failure times are assumed to arise from $\exp(\lambda)$, i.e., $f_T(t)=\lambda \exp(-\lambda t)$.

- Computing MLE

 - 1. $f(t_i; \lambda) = \lambda \exp(-\lambda t_i), i = 1, ..., 10$ 2. $L(\lambda) = \prod_{i=1}^{10} f(t_i; \lambda) = \lambda^{10} \exp(-\lambda \sum_{i=1}^{10} t_i)$ 3. $\ell(\lambda) = \sum_{i=1}^{10} \ln f(t_i; \lambda) = 10 \times (\ln \lambda) \lambda \sum_{i=1}^{10} t_i$ $-\ell'(\lambda) = 10/\lambda \sum_{i=1}^{10} t_i$

 - 4. $\hat{\lambda}_{\text{ML}} = \arg\max_{\lambda \in (0,\infty)} \ell(\lambda)$ $-\hat{\lambda}_{\text{ML}} = 10/\sum_{i=1}^{10} t_i = 10/88$ by solving the score equation $\ell'(\lambda) = 0$
- 95% CI of λ
 - 1. $\ell''(\lambda) = -10/\lambda^2$
 - 2. $I(\lambda) = -E\ell''(\lambda) = 10/\lambda^2$
 - 3. 95% CI of λ : $\hat{\lambda}_{\rm ML} \pm 1.96 \times I(\hat{\lambda}_{\rm ML})^{-1/2}$, i.e., $10/88 \pm 1.96 \times \sqrt{10}/88$
 - Because $\lambda \approx N(\hat{\lambda}_{ML}, I(\hat{\lambda}_{ML})^{-1}) = N(10/88, 10/88^2)$
 - 4. Interpretation
- Testing $H_0: \lambda = .1$ vs $H_1: \lambda \neq .1$ at the significance level $\alpha = .05$

- 1. Test statistic: $2\{\ell(\hat{\lambda}_{\mathrm{ML}}) \ell(\hat{\lambda}_{\mathrm{ML},H_0})\} \approx .16$ $- \hat{\lambda}_{\mathrm{ML},H_0} = .1$
- 2. Compare the value of test statistic with $\chi^2_{p,1-\alpha}$ $-\chi^2_{p,1-\alpha} \approx 3.84$ with p=1
- 3. Or, the p-value may be calculated via pchisq(.16, 1)
- 4. Conclusion

Likelihood principles (for right-censored data)

- Observed $\widetilde{T}_i = \widetilde{t}_i$ and $\Delta_i = \delta_i$ (event indicator),
 - $-\widetilde{T}_i$: the smaller one between T_i (event time) and C_i (right-cencoring time)
 - Assuming the independence across i
 - Assuming the independent and noninformative censoring, i.e.,
 - * $T_i \perp C_i$ (conditional on covariates)
 - * $S_{T_i}(t \mid \boldsymbol{\theta})$ and $S_{C_i}(t \mid \boldsymbol{\eta})$ have NO common parameter
- Joint density of T_i and Δ_i : $f_{\widetilde{T}_i,\Delta_i}(\tilde{t}_i,\delta_i) =$
 - $f_{T_i}(\tilde{t}_i \mid \boldsymbol{\theta}) S_{C_i}(\tilde{t}_i \mid \boldsymbol{\eta}) \text{ if } \delta_i = 1$
 - $-S_{T_i}(\tilde{t}_i \mid \boldsymbol{\theta}) f_{C_i}(\tilde{t}_i \mid \boldsymbol{\eta}) \text{ if } \delta_i = 0$
 - * Because
 - $\operatorname{Pr}(\widetilde{T}_i > t, \Delta_i = 1) = \operatorname{Pr}(C_i \geq T_i, T_i > t) = \int_t^\infty \operatorname{Pr}(C_i \geq u, T_i = u) du = \int_t^\infty S_{C_i}(u)$
 - $\Pr(\widetilde{T}_i > t, \Delta_i = 0) = \Pr(T_i \ge C_i, C_i > t) = \int_t^\infty \Pr(T_i \ge u, C_i = u) du = \int_t^\infty S_{T_i}(u \mid t) dt$ $\boldsymbol{\theta}) f_{C_i}(u \mid \eta) du$
- Observed-data likelihood: $L(\boldsymbol{\theta}, \boldsymbol{\eta}) = \prod_{i=1}^{n} f_{\widetilde{T}_{i}, \Lambda_{i}}(\widetilde{t}_{i}, \delta_{i}) = \prod_{i=1}^{n} \{f_{T_{i}}(\widetilde{t} \mid \boldsymbol{\theta}) S_{C_{i}}(\widetilde{t} \mid \boldsymbol{\eta})\}^{\delta_{i}} \{S_{T_{i}}(\widetilde{t} \mid \boldsymbol{\theta}) f_{C_{i}}(\widetilde{t} \mid \boldsymbol{\theta})\}^{\delta_{i}} \{S_{T_{i}}(\widetilde{t} \mid \boldsymbol{\theta})\}^{\delta_{i}} \{S_{T_$
 - Reducing to $\prod_{i=1}^n f_{T_i}(\tilde{t}_i \mid \boldsymbol{\theta})^{\delta_i} S_{T_i}(\tilde{t}_i \mid \boldsymbol{\theta})^{1-\delta_i} = \prod_{i=1}^n \lambda_{T_i}(\tilde{t}_i \mid \boldsymbol{\theta})^{\delta_i} S_{T_i}(\tilde{t}_i \mid \boldsymbol{\theta})$ if we are only concerned about the MLE of θ

Ex. 4.2. Exponential regression for right-censored data

- Observed $\{\widetilde{T}_i = t_i, \Delta_i = \delta_i, x_{i1}, \dots, x_{in}\}$

 - $-\widetilde{T}_i = \min(T_i, C_i)$ $-\Delta_i = 1$ if $\widetilde{T}_i = T_i$ and zero otherwise
- Assuming independent and non-informative censoring
- Assuming $T_i \sim \exp(\lambda_i)$
 - $-\lambda_i = \exp(\beta_0 + \sum_{j=1}^p x_{ij}\beta_j)$ (Why using the exponential form?) Hazard rate $\lambda_{T_i}(t \mid \beta) = \lambda_i$

 - Survival function $S_{T_i}(t \mid \boldsymbol{\beta}) = \exp(-\lambda_i t)$
- Likelihood function $L(\beta) = \prod_i \lambda_{T_i}(t_i \mid \beta)^{\delta_i} S_{T_i}(t_i \mid \beta)$
 - $-\beta = [\beta_0, \beta_1, \dots, \beta_n]^{\top}$
- Log-likelihood function $\ell(\beta) = \sum_{i} \{\delta_i \ln \lambda_{T_i}(t_i \mid \beta) + \ln S_{T_i}(t_i \mid \beta)\} = \sum_{i} \{\delta_i(\beta_0 + \sum_{j=1}^p x_{ij}\beta_j) \sum_{j=1}^p x_{ij}\beta_j\}$ $t_i \exp(\beta_0 + \sum_{j=1}^p x_{ij}\beta_j)$
 - Score function $U(\boldsymbol{\beta}) = \frac{\partial \ell(\boldsymbol{\beta})}{\partial \boldsymbol{\beta}} = \left[\frac{\partial \ell(\boldsymbol{\beta})}{\partial \beta_0}, \frac{\partial \ell(\boldsymbol{\beta})}{\partial \beta_1}, \dots, \frac{\partial \ell(\boldsymbol{\beta})}{\partial \beta_p}\right]^{\top}$
 - * In general no closed-form for the solution of score equations $U(\beta) = 0$
 - Fisher information $I(\beta) = -E \frac{\partial \ell(\beta)}{\partial \beta \partial \beta^{\top}}$
 - $* \frac{\partial \ell(\beta)}{\partial \beta \partial \beta^{\top}} = [\frac{\partial \ell(\beta)}{\partial \beta_i \partial \beta_j}]_{(p+1) \times (p+1)}$ Newton's method (for maximization)

- 1. Start with an initial guess $\hat{\beta}_{(0)}$
- 2. Update the current estimate with $\hat{\boldsymbol{\beta}}_{(k+1)} = \hat{\boldsymbol{\beta}}_{(k)} + I(\hat{\boldsymbol{\beta}}_{(k)})^{-1}U(\boldsymbol{\beta}_{(k)})$ until $\hat{\boldsymbol{\beta}}_{(k)}$ and $\hat{\boldsymbol{\beta}}_{(k+1)}$ are close enough

Likelihood principles (for general censored data)

- Assuming the independence across i and noninformative censoring
- Observed-data likelihood:

$$\prod_{i\in\mathfrak{D}}f_{T_i}(\tilde{t}_i)\prod_{i\in\mathfrak{R}}S_{T_i}(\tilde{t}_i)\prod_{i\in\mathfrak{L}}\{1-S_{T_i}(\tilde{t}_i)\}\prod_{i\in\mathfrak{I}}\{S_{T_i}(\tilde{t}_{iL})-S_{T_i}(\tilde{t}_{iR})\}$$

- $-\mathfrak{D}$: the set of **unobserved** subjects
- $-\Re$: the set of **right-censored** subjects
- $\mathfrak L$ the set of **left-censored** subjects
- 3: the set of **interval-censored** subjects

A special case of utilizing AFT models

- A covariate for grouping, e.g., $x_{i1} = k$ for group k, k = 1, ..., K
- Wish to compare the survival in K groups
- Ex 4.3. ([DM] pp.147): The purpose of Steinberg et al. (2009) was to evaluate extended duration of a triple-medication combination versus therapy with the nicotine patch alone in smokers with medical illnesses.

```
head(asaur::pharmacoSmoking)
data.ex43 = asaur::pharmacoSmoking
data.ex43 = data.ex43[data.ex43$ttr != 0,] # ttr=0 not allowed in AFT models
is.factor(data.ex43$grp)
aft.ex43 = survival::survreg(
  survival::Surv(ttr, relapse) ~ grp,
  data = data.ex43,
  dist="weibull"
)
summary(aft.ex43) # Confused about "scale" in the output? Check ?survival::survreg.distributions
# OR using flexsurv::flexsurvreg
aft.ex43.2 = flexsurv::flexsurvreg(
  survival::Surv(ttr, relapse) ~ grp,
  data = data.ex43,
  dist = "weibull"
)
aft.ex43.2
survminer::ggflexsurvplot(aft.ex43.2)
# prediction for grp='combination'
shape = 1/aft.ex43$scale
scale = unname(exp(aft.ex43$coefficients[1])) # scale
(ET = scale*gamma(1+1/shape)) # expectation of T
(medT = scale*log(2)^(1/shape)) # median of T
surv.fun = function(t){ # survival function
  return(
    1-pweibull(t, shape = shape, scale = scale)
```

```
)
}
curve(surv.fun, from = 0, to = 1e3) # plot the survival curve for grp='combination'
```

• Ex. 4.4. (Revisiting the data of Bladder Cancer Recurrences) A dataset on recurrences of bladder cancer. It contains three treatment arms for 118 subjects.

```
data.ex44 = survival::bladder1[
  complete.cases(
    survival::bladder1[,c('id', 'treatment', 'start', 'stop', 'status')]
  c('id', 'treatment', 'start', 'stop', 'status')
1
data.ex44\$status = 1*(data.ex44\$status \%in% c(1,2,3)) # merging status 1, 2,3
data.ex44$tte = data.ex44$stop - data.ex44$start
data.ex44 = data.ex44[data.ex44$tte != 0,] # ttr=0 not allowed in AFT models
is.factor(data.ex44$treatment)
aft.ex44 = survival::survreg(
  survival::Surv(tte, status) ~ treatment,
  data = data.ex44,
 dist="lognormal"
summary(aft.ex44)
# OR using flexsurv::flexsurvreg
aft.ex44.2 = flexsurv::flexsurvreg(
  survival::Surv(tte, status) ~ treatment,
 data = data.ex44,
 dist = "lnorm"
)
aft.ex44.2
survminer::ggflexsurvplot(aft.ex44.2)
# prediction for treatment='pyridoxine'
sigma = aft.ex44$scale
mu = sum(aft.ex44$coefficients[1:2]) # scale
(ET = exp(mu+sigma^2/2)) # expectation of T
(medT = exp(mu)) # median of T
surv.fun = function(t){ # survival function for treatment='pyridoxine'
  return(
    1-pnorm((log(t)-mu)/sigma)
}
curve(surv.fun, from = 0, to = 1e2) # plot the survival curve
```

Pros and cons

- Likelihood principles
 - Clear pathway
 - Exact inference only available for selected (and really simple) cases, i.e., approximations usually employed
 - MLE considered (approximately) the most efficient in regular cases
 - LRT optimal for simple cases but well accepted even in complex cases
- AFT model

- Easy to interprete coeffcients: effects on the failure time directly
- Distribution assumptions may be too strong
- Can handle non-standard situations such interval censoring
- Yields estimates of functions like hazard and survival for all times (even beyond the scope of follow-up)
 - * Also dangerous since the extrapolation beyond the observed data range is not reliable
